

Transport across cell membranes 3

Level: OCR A Level H420

Subject: Biology

Exam Board: Suitable for all boards

Topic: Transport across cell membranes 3

Type: Questionnaire

To be used by all students preparing for OCR A Level Biology H420 foundation or higher tier but also suitable for students of other boards.

(a) The structure of a plasma membrane is described as a fluid mosaic. Explain why.

| | | |
|------|------|--|
| | | |
| | | |
| | | |
| | | |

(2)

(b) Give **two** functions of proteins in plasma membranes.

| 1. | | | |
|----|--|--|--|
| | | | |

(2)

Scientists investigated the movement of calcium ions across the plasma membrane of human cells. They placed human cells in a solution of calcium ions. At regular intervals, they measured the concentration of calcium ions in the external solution and the concentration of calcium ions inside the cells. Their results are shown in the graph.

(c) By what process did the calcium ions leave the cells after 10 minutes? Use evidence from the graph to support your answer.

| | | |
|------|------|--|
| | | |
| | | |
| | | |
| | | |

(Total 6 marks)

The diagram shows one method by which amino acids are absorbed from the small intestine into the blood. They are co-transported into the epithelial cell with sodium ions (Na⁺) at point **X** on the diagram. Normally, the concentration of sodium ions inside the epithelial cell is low.

Source: adapted from M. ROWLAND, Biology (University of Bath Science 16-19) (Nelson Thornes) 1992.

Dinitrophenol (DNP) prevents oxidative phosphorylation. When treated with DNP, the sodium-potassium pump at **Y** no longer works. As a result, the concentration of sodium ions in the cell rises and amino acid absorption stops.

| (ii) | Explain why sodium ions and amino acids are not absorbed from the lumen of the intestine in the presence of DNP. | e small |
|--|---|------------------------|
| | | |
| (iii) | By what mechanism would amino acids leave the epithelial cell at point Z ? | (2) |
| (111) | | |

| Read | d the following passage. | |
| the | plasma membrane plays a vital role in microorganisms. It forms a barrier between cell and its environment, controlling the entry and exit of solutes. s makes bacteria vulnerable to a range of antiseptics and antibiotics. | |
| mer mar con mer plas | en bacteria are treated with antiseptics, the antiseptics bind to the proteins in the imbrane and create tiny holes. Bacteria contain potassium ions at a concentration by times that outside the cell. Because of the small size of these ions and their centration in the cell, the first observable sign of antiseptic damage to the plasma in the leaking of potassium ions from the cell. Some antibiotics damage the sma membrane in a similar way. One of these is tyrocidin. This is a cyclic repetide consisting of a ring of ten amino acids. Tyrocidin and other polypeptide | 5 10 |
| | biotics are of little use in medicine. | 10 |
| thou synt forn pota med | er antibiotics also increase the rate of potassium movement from cells. It is ught that potassium ions are very important in energy release and protein thesis, and a loss of potassium ions would lead to cell death. Gramicidin A coils to a permanent pore passing through the plasma membrane. This pore enables assium ions to be conducted from the inside of the cell into the surrounding dium. Vanilomycin also facilitates the passage of potassium ions from the cell. solecule of vanilomycin forms a complex with a potassium ion and transports it | 15 |
| acro van | oss the membrane. The potassium ion is released on the outside and the ilomycin is free to return and pick up another potassium ion. Vanilomycin depends he fluid nature of the plasma membrane in order to function. | 20 |
| diffe stro regi lipid orga | yene antibiotics have flattened ring-shaped molecules. The two sides of the ring er from each other. One side consists of an unsaturated carbon chain. This part is ngly hydrophobic and rigid. The opposite side is a flexible, strongly hydrophilic on. It has been shown that polyene antibiotics bind only to sterols. Sterols are its found in the membranes of eukaryotes but not in the membranes of prokaryotic enisms. It is thought that several sterol-polyene complexes come together. | 25 |

the ability to act as selective barriers and small ions and molecules rapidly leak out.

Use information in the passage and your own knowledge to answer the questions.

| i) Draw a peptide bond showing how the COOH group of one amino acid joins to the NH ₂ group of another. | | |
|--|-----|---|
| Experiments have shown that vanilomycin is unable to transport potassium ions across a | i) | |
| Experiments have shown that vanilomycin is unable to transport potassium ions across a | ii) | How many peptide bonds are there in a molecule of tyrocidin (lines 9 - 10)? |
| | | |
| | | |

(d) Draw a simple diagram of one of the phospholipid layers to show how polyene antibiotics allow small ions and molecules to leak rapidly through a plasma membrane. Use the following symbols to represent the different molecules.

Note that the zigzag line on the symbol for the polyene antibiotic represents its hydrophobic region.

Read the following passage.

Human milk contains all the nutrients a young baby needs in exactly the right proportions. It is formed in the mammary glands by small groups of milk-producing cells. These cells absorb substances from the blood and use them to synthesise the lipids, carbohydrates and proteins found in milk. Milk-producing cells are roughly cube-shaped and have a height to breadth ratio of approximately 1.2:1.

The main carbohydrate in milk is lactose. Lactose is a disaccharide formed by the condensation of two monosaccharides, glucose and galactose. (A molecule of galactose has the same formula as a molecule of glucose – the atoms are just arranged in a different way.)

10 Lactose is synthesised in the Golgi apparatus and transported in vesicles through the cytoplasm. Because lactose is unable to escape from these vesicles, they increase in diameter as they move towards the plasma membrane. The vesicle membranes fuse with the plasma membrane and the vesicles empty their contents out of the cell.

Use the information from the passage and your own knowledge to answer the following questions.

| • | | | |
|-----|------|--|------|
| (a) | (i) | The breadth of a milk-producing cell is 26 µm. Calculate the height of this cell. | |
| | | Height = μm | (1 |

16

An investigation was carried out to compare the uptake of sulphate ions by barley roots in aerobic and in anaerobic conditions. The results are shown in the graph.

| Explain the evidence from the graph that active transport is involved in the uptake of sulphate ions. | |
|---|------|
| | |
| | |
| | |
| Suggest why the uptake of sulphate ions by the roots in anaerobic conditions stopped af 3 hours. | fter |

(1) (Total 3 marks)

Glasswort is a plant that grows in salt marshes. The plants are covered by seawater at each high tide. The roots grow in mud which contains a high concentration of salt. The drawing shows a shoot of the plant.

In glasswort cells, sodium ions are transported from the cytoplasm outwards across the cell surface membrane and also into the cell vacuole. The concentration of sodium ions is greater inside the vacuole than in the intercellular fluid, which is the fluid between the cells in tissues. High sodium ion concentrations would disrupt metabolic processes in the cytoplasm. This information is summarised in the diagram below.

| S | (a) | The total concentration of all ions in the cytoplasm is higher than in the intercellular fluid |
|---|-----|--|
| | | Explain how this allows the cell to take up water. |

| S | (b) | (i) | Explain how sodium ions are transported through the membranes. | |
|---|-----|------|---|-----|
| | | | | |
| | | | | |
| | | | | |
| | | | | (2) |
| | | (ii) | There is a higher concentration gradient between the cytoplasm and the vacuole than between the cytoplasm and the intercellular fluid. Suggest how the vacuole membrane maintains this higher concentration gradient. | |
| | | | | |
| | | | | |
| | | | | |
| | | | | (2) |

S Penstemon plants have mechanisms that regulate the amount of nectar produced by their flowers. Nectar is a solution containing sucrose which attracts insect pollinators. The diagram shows a section through a penstemon flower.

To investigate these mechanisms the volume of nectar produced was determined. A thin strip of filter paper was dipped into the nectar until all the nectar was absorbed. The distance the nectar moved up the paper was measured. The actual volume of nectar was found by reading the value from a calibration curve on a graph. A sucrose solution similar to nectar was used to produce this calibration curve.

| (a) | (i) | The solution contained 22% by mass of sucrose. Describe how you would make 50 cm ³ of this solution. | • |
|-----|------|---|-----|
| | | | |
| | | | (1) |
| | (ii) | Describe how you would use the solution to produce the calibration curve. | |
| | | | |
| | | | |

(2)

In one experiment the effect of removing nectar at regular intervals was investigated. First all the nectar was removed from two penstemon flowers. From one flower (A) all the nectar produced was removed each hour for the next six hours. In the second flower (B) the nectar was allowed to accumulate for six hours. Each time the nectar was removed, the sugar was extracted from the strip of filter paper and its mass was measured. The graphs show the results.

| (b) | (i) | Describe the effects on nectar production and on sucrose secretion of removing the nectar every hour compared with removing it after 6 hours. |
|-----|-----|---|
| | | |
| | | |

How would the nectar collected after 6 hours from plant B differ from that collected (ii) after 6 hours from plant A.

The graph shows the effect of concentration on the rate of uptake of magnesium ions by root hair cells.

(b) For curve **Y** name the process the cells are using to absorb magnesium ions between concentrations **A** and **B**. Use information in the graph to explain your answer.

| In the solution without oxygen, explain why no magnesium ions are taken up between concentrations A and B . |
|---|
| In the solution without oxygen, explain why no magnesium ions are taken up between concentrations A and B . |
| concentrations A and B . |
| |
| For curve Z explain why the rate of uptake increases between B and C . |

- IAA is an auxin which stimulates plant growth. It binds to proteins in cell walls. This changes the arrangement of the cellulose molecules, so the walls are more easily stretched. IAA also lowers the pH around the cells.
 - 2,4-D is a systemic herbicide which has the same effect on cell walls as IAA, but it is less easily broken down in plants.
- **S** (a) The diagram shows the molecular structures of IAA and 2,4-D.

Use evidence from the diagram to suggest

| (i) | why IAA lowers pH; |
|------|---|
| (ii) | why IAA and 2,4-D have similar effects on cell walls. |
| time | en 2,4-D is applied to weeds their growth is very rapid but very distorted. After a short they die. Suggest one explanation for the rapid and distorted growth of weeds when D is applied. |

Tomato growers have increased the yield of fruit from 100 to 400 tonnes per hectare by growing the tomato plants in automatically heated glasshouses and enhancing the carbon dioxide concentration. To control the nutrient supply to the roots, the plants are grown without soil in plastic troughs, as shown in the diagram.

| (a) | Explain how enhancing the carbon dioxide concentration helps to increase the yield. | |

S Gorter and Grendel investigated the structure of the surface membrane of cells. They extracted the phospholipids from the surface membranes of red blood cells in 1 cm³ of blood and placed them in the apparatus shown in **Figure 1**.

Figure 1

The piston was pushed across the surface of the water until the phospholipid molecules were tightly packed into a single layer. The area covered by the phospholipid molecules was measured. This area was compared with the estimated surface area of the red blood cells from which phospholipids were extracted.

Gorter and Grendel obtained the data shown in the table.

30

| Number of red blood cells per cm ³ of blood | 4.74 × 10 ⁹ |
|---|------------------------|
| Estimated mean surface area of one red blood cell | 99.4 μm² |
| Surface area of membrane phospholipids extracted from 1cm ³ of blood | 0.92 m ² |

Some strains of the bacterium that causes gonorrhoea are resistant to antibiotics. This makes the disease difficult to treat. One way of testing the effectiveness of antibiotics is to use discs of paper soaked in antibiotic. These are placed in the centre of an agar plate covered by bacteria. A clear zone forms around the disc if the antibiotic is effective.

The table shows some results of an investigation into the effect of four different antibiotics on gonorrhoea bacteria.

| Antibiotic | Diameter of clear zone / mm | Minimum diameter of clear zone if antibiotic is effective / mm |
|------------|-----------------------------|--|
| Α | 47 | 52 |
| В | 30 | 28 |
| С | 22 | 40 |
| D | 33 | 34 |
